Model-mommy offers you a smart way to create fixtures for testing in Django. With a simple and powerful API you can create many objects with a single line of code.

Contents 1

2 Contents

CHAPTER 1	
-----------	--

Contributing to Model Mommy

As an open source project, Model Mommy welcomes contributions of many forms Examples of contributions include:

- Code Patches
- Documentation improvements
- Bug reports

CHAPTER	2
----------------	---

Install

Run the command above

pip install model_mommy

6 Chapter 2. Install

Contributing

1. Prepare a virtual environment.

pip install virtualenvwrapper
mkvirtualenv model_mommy --no-site-packages --distribute

2. Install the requirements.

pip install -r dev_requirements.txt

3. Run the tests.

make test

CHAPTER 4	
Inspiration	

Model-mommy was inspired by many great open source software like ruby's ObjectDaddy and FactoryGirl.

Doubts? Loved it? Hated it? Suggestions?

Join our mailing list for support, development and ideas!

• https://groups.google.com/group/model-mommy

Contents:

5.1 Basic Usage

Let's say you have an app family with a model like this:

File: model.py

```
class Kid(models.Model):
    """
    Model class Kid of family app
    """
    happy = models.BooleanField()
    name = models.CharField(max_length=30)
    age = models.IntegerField()
    bio = models.TextField()
    wanted_games_qtd = models.BigIntegerField()
    birthday = models.DateField()
    appointment = models.DateTimeField()
```

To create a persisted instance, just call Mommy:

File: test_model.py

```
# -*- coding:utf-8 -*-
#Core Django imports
from django.test import TestCase
#Third-party app imports
from model_mommy import mommy
from model_mommy.recipe import Recipe, foreign_key
# Relative imports of the 'app-name' package
from .models import Kid
class KidTestModel(TestCase):
```

```
Class to test the model
Kid
"""

def setUp(self):
    """
    Set up all the tests
    """
    self.kid = mommy.make(Kid)
```

No need to pass attributes every damn time.

Importing every model over and over again is boring. So let Mommy import them for you:

```
from model_mommy import mommy
# 1st form: app_label.model_name
kid = mommy.make('family.Kid')
# 2nd form: model_name
dog = mommy.make('Dog')
```

Note: You can only use the 2nd form on unique model names. If you have an app family with a Dog, and an app farm with a Dog, you must use the app_label.model_name form.

Note: model_name is case insensitive.

5.1.1 Model Relationships

Mommy also handles relationships. Say the kid has a dog:

File: model.py

```
class Kid (models.Model):
    Model class Kid of family app
   happy = models.BooleanField()
   name = models.CharField(max_length=30)
   age = models.IntegerField()
   bio = models.TextField()
   wanted_games_qtd = models.BigIntegerField()
   birthday = models.DateField()
   appointment = models.DateTimeField()
    class Meta:
        verbose_name = _(u'Kid')
        verbose_name_plural = _(u'Kids')
    def __unicode__(self):
        Retorn the name of kid
        return u' %s' % (self.name)
class Dog(models.Model):
```

```
Model class Dog of family app
    owner = models.ForeignKey('Kid')
when you ask Mommy:
File: test_model.py
# -*- coding:utf-8 -*-
#Core Django imports
from django.test import TestCase
#Third-party app imports
from model_mommy import mommy
from model_mommy.recipe import Recipe, foreign_key
# Relative imports of the 'app-name' package
class DogTestModel (TestCase):
    Class to test the model
   Dog
    n n n
    def setUp(self):
        Set up all the tests
        self.rex = mommy.make('family.Dog')
```

She will also create the Kid, automagically.

5.1.2 M2M Relationships

```
File: test_model.py

# -*- coding:utf-8 -*-

#Core Django imports

from django.test import TestCase

#Third-party app imports

from model_mommy import mommy

from model_mommy.recipe import Recipe, foreign_key

# Relative imports of the 'app-name' package

class DogTestModel(TestCase):

"""

Class to test the model

Dog

"""

def setUp(self):

"""

Set up all the tests
```

5.1. Basic Usage

```
self.rex = mommy.make('family.Dog', make_m2m=True)
```

5.1.3 Defining some attributes

Of course it's possible to explicitly set values for attributes.

```
File: test_model.py
```

```
# -*- coding:utf-8 -*-
#Core Django imports
from django.test import TestCase
#Third-party app imports
from model_mommy import mommy
from model_mommy.recipe import Recipe, foreign_key
# Relative imports of the 'app-name' package
from .models import Kid
class KidTestModel(TestCase):
    Class to test the model
   Kid
   def setUp(self):
        Set up all the tests
        self.kid = mommy.make(
           Kid,
           age=3
        self.another_kid = mommy.make(
           'family.Kid',
            age=6
```

Related objects attributes are also reachable:

File: test_model.py

```
# -*- coding:utf-8 -*-
#Core Django imports
from django.test import TestCase

#Third-party app imports
from model_mommy import mommy
from model_mommy.recipe import Recipe, foreign_key
# Relative imports of the 'app-name' package
from .models import Dog

class DogTestModel(TestCase):
```

```
"""
Class to test the model
Dog
"""

def setUp(self):
    """
    Set up all the tests
    """

self.bobs_dog = mommy.make(
    'family.Dog',
    owner__name='Bob'
)
```

5.1.4 Non persistent objects

If don't need a persisted object, Mommy can handle this for you as well:

```
from model_mommy import mommy
kid = mommy.prepare('family.Kid')
```

It works like *make*, but it doesn't persist the instance.

5.1.5 More than one instance

If you need to create more than one instance of the model, you can use the _quantity parameter for it:

```
from model_mommy import mommy
kids = mommy.make('family.Kid', _quantity=3)
assert len(kids) == 3

It also works with prepare:
from model_mommy import mommy
kids = mommy.prepare('family.Kid', _quantity=3)
assert len(kids) == 3
```

5.2 How mommy behaves?

By default, *model-mommy* skips fields with *null=True* or *blank=True*. Also if a field has a *default* value, it will be used.

You can override this behavior by:

1. Explicitly defining values

```
# from "Basic Usage" page, assume all fields either null=True or blank=True
from .models import Kid
from model_mommy import mommy
kid = mommy.make(Kid, happy=True, bio='Happy kid')
```

2. Passing _fill_optional with a list of fields to fill with random data

```
kid = mommy.make(Kid, _fill_optional=['happy', 'bio'])
```

3. Passing _fill_optional=True to fill all fields with random data

```
kid = mommy.make(Kid, _fill_optional=True)
```

5.2.1 When shouldn't you let mommy generate things for you?

If you have fields with special validation, you should set their values by yourself.

Model-mommy should handle fields that:

- 1. don't matter for the test you're writing;
- 2. don't require special validation (like unique, etc);
- 3. are required to create the object.

5.2.2 Currently supported fields

- BooleanField, IntegerField, BigIntegerField, SmallIntegerField, PositiveIntegerField, PositiveSmallIntegerField, PositiveIntegerField, PositiveIntegerFi
- CharField, TextField, SlugField, URLField, EmailField, IPAddressField, GenericIPAddressField
- ForeignKey, OneToOneField, ManyToManyField (even with through model)
- · DateField, DateTimeField, TimeField
- FileField, ImageField

5.2.3 Custom fields

Model-mommy allows you to define generators methods for your custom fields or overrides its default generators. This could be achieved by specifing a dict on settings that its keys are the field paths and the values their generators functions, as the example bellow:

```
# on your settings.py file:
def gen_func():
    return 'value'

MOMMY_CUSTOM_FIELDS_GEN = {
    'test.generic.fields.CustomField': gen_func,
}
```

5.3 Recipes

If you're not comfortable with random data or even you just want to improve the semantics of the generated data, there's hope for you.

You can define a recipe, which is a set of rules to generate data for your models. Create a module called mommy recipes.py at your app's root directory:

```
fixtures/
migrations/
templates/
tests/
__init__.py
admin.py
managers.py
models.py
mommy_recipes.py
urls.py
views.py
File: mommy_recipes.py
from model_mommy.recipe import Recipe
from family.models import Person
person = Recipe(
   Person,
   name = 'John Doe',
   nickname = 'joe',
   age = 18,
    birthday = date.today(),
    appointment = datetime.now()
```

Note: You don't have to declare all the fields if you don't want to. Omitted fields will be generated automatically.

```
File: test_model.py
```

```
# -*- coding:utf-8 -*-
#Core Django imports
from django.test import TestCase
#Third-party app imports
from model mommy import mommy
from model_mommy.recipe import Recipe, foreign_key
# Relative imports of the 'app-name' package
from .models import Person, Contact
class PersonTestModel(TestCase):
   Class to test the model
   Person
   def setUp(self):
       Set up all the tests
       self.person_one = mommy.make_recipe(
           'family.person'
        self.person_simpsons = Recipe(
            Person,
```

5.3. Recipes 17

```
name='Moe',
)

self.contact = Recipe(
    Contact,
    person=foreign_key(self.person_simpsons),
    tel='3333333eeeeR'
)

def test_kind_contact_create_instance(self):
    """
    True if create instance
    """
    contact = self.contact.make()
    self.assertIsInstance(contact, Contact)
```

Or if you don't want a persisted instance:

```
from model_mommy import mommy
mommy.prepare_recipe('family.person')
```

Another examples

Note: You can use the _quantity parameter as well if you want to create more than one object from a single recipe.

Note: You can define recipes locally to your module or test case as well. This can be useful for cases where a particular set of values may be unique to a particular test case, but used repeatedly there.

Look:

```
File: mommy recipes.py
company_recipe = Recipe(Company, name='WidgetCo'
File: test_model.py
class EmployeeTest (TestCase):
    def setUp(self):
        self.employee_recipe = Recipe(
            Employee,
            name=seq('Employee'),
            company=company_recipe.make()
        )
    def test_employee_list(self):
        self.employee_recipe.make(_quantity=3)
        # test stuff....
    def test_employee_tasks(self):
        employee1 = self.employee_recipe.make()
        task_recipe = Recipe(Task, employee=employee1)
        task_recipe.make(status='done')
        task_recipe.make(due_date=datetime(2014, 1, 1))
        # test stuff....
```

5.3.1 Recipes with foreign keys

You can define *foreign_key* relations:

```
from model_mommy.recipe import Recipe, foreign_key
from family.models import Person, Dog

person = Recipe(Person,
    name = 'John Doe',
    nickname = 'joe',
    age = 18,
    birthday = date.today(),
    appointment = datetime.now()
)

dog = Recipe(Dog,
    breed = 'Pug',
    owner = foreign_key(person)
)
```

Notice that person is a recipe.

You may be thinking: "I can put the Person model instance directly in the owner field". That's not recommended.

Using the *foreign_key* is important for 2 reasons:

- Semantics. You'll know that attribute is a foreign key when you're reading;
- The associated instance will be created only when you call make_recipe and not during recipe definition;

You can also use *related*, when you want two or more models to share the same parent:

Note this will only work when calling *make_recipe* because the related manager requires the objects in the related_set to be persisted. That said, calling *prepare_recipe* the related_set will be empty.

If you want to set m2m relationship you can use *related* as well:

```
class Dog(models.Model):
    owner = models.ForeignKey('Person')
    breed = models.CharField(max_length=50)
    created = models.DateTimeField(auto_now_add=True)
    friends_with = models.ManyToManyField('Dog')

from model_mommy.recipe import related, Recipe

dog = Recipe(Dog,
    breed = 'Pug',
```

5.3. Recipes 19

```
dog_with_friends = dog.extend(
    friends_with=related(dog, dog),
```

5.3.2 Recipes with callables

It's possible to use *callables* as recipe's attribute value.

```
from datetime import date
from model_mommy.recipe import Recipe
from family.models import Person

person = Recipe(Person,
    birthday = date.today,
)
```

When you call *make_recipe*, *Mommy* will set the attribute to the value returned by the callable.

5.3.3 Recipes with iterators

You can also use *iterators* (including *generators*) to provide multiple values to a recipe.

Mommy will use the next value in the *iterator* every time you create a model from the recipe.

5.3.4 Sequences in recipes

Sometimes, you have a field with an unique value and using *make* can cause random errors. Also, passing an attribute value just to avoid uniqueness validation problems can be tedious. To solve this you can define a sequence with *seq*

```
from model_mommy.recipe import Recipe, seq
from family.models import Person

person = Recipe(Person,
    name = seq('Joe'),
    age = seq(15)
)

p = mommy.make_recipe('myapp.person')
p.name
>>> 'Joe1'
p.age
>>> 16

p = mommy.make_recipe('myapp.person')
p.name
>>> 'Joe2'
```

```
p.age
>>> 17
```

This will append a counter to strings to avoid uniqueness problems and it will sum the counter with numerical values.

You can also provide an optional *increment_by* argument which will modify incrementing behaviour. This can be an integer, float, Decimal or timedelta.

```
from datetime import datetime, timedelta
from model_mommy.recipe import Recipe, seq
from family.models import Person
person = Recipe (Person,
    age = seq(15, increment_by=3)
    height_ft = seq(5.5, increment_by=.25)
    # assume today's date is 21/07/2014
    appointment = seq(datetime.date(2014, 7, 21), timedelta(days=1))
)
p = mommy.make_recipe('myapp.person')
p.age
>>> 18
p.height_ft
>>> 5.75
p.appointment
>>> datetime.date(2014, 7, 22)
p = mommy.make_recipe('myapp.person')
p.age
>>> 21
p.height_ft
>>> 6.0
p.appointment
>>> datetime.date(2014, 7, 23)
```

Note: If your Python's interpreter version is 2.6.x or earlier then *increment_by* is not available for you. *seq* will simply ignore this argument.

5.3.5 Overriding recipe definitions

Passing values when calling *make recipe* or *prepare recipe* will override the recipe rule.

```
from model_mommy import mommy
mommy.make_recipe('model_mommy.person', name='Peter Parker')
```

This is useful when you have to create multiple objects and you have some unique field, for instance.

5.3.6 Recipe inheritance

If you need to reuse and override existent recipe call extend method:

```
dog = Recipe(Dog,
    breed = 'Pug',
    owner = foreign_key(person)
```

5.3. Recipes 21

```
extended_dog = dog.extend(
    breed = 'Super basset',
)
```

5.4 Deprecation Warnings

Because of the changes of model_mommy's API, the following methods are deprecated and will be removed in one of the future releases:

- mommy.make_one -> should use the method mommy.make instead
- mommy.prepare_one -> should use the method mommy.prepare instead
- mommy.make_many -> should use the method mommy.make with the _quantity parameter instead
- mommy.make_many_from_recipe -> should use the method mommy.make_recipe with the _quantity parameter instead

5.5 Known Issues

5.5.1 django-taggit

Model-mommy identifies django-taggit's TaggableManager as a normal Django field, which can lead to errors:

```
TypeError: <class 'taggit.managers.TaggableManager'> is not supported by mommy.
```

The fix for this is to set blank=True on your TaggableManager.

5.6 Extensions

5.6.1 GeoDjango

Works with it? This project has some custom generators for it: https://github.com/sigma-consultoria/mommy_spatial_generators

CHAPTER 6

Indices and tables

- genindex
- modindex
- search
